

Practical 7 Networking and Web Services

Create a new project “Practical7” in Android Studio:

1. Create an application to load and display an HTML code from the internet.

Find a public web service API:

2. Create an application that communicates with the publicly available web service using GET method and gets the result displayed.

Create a Supabase project (www.supabase.com) for hosting a database in the cloud, then create a table with one auto-increment ID, and 3 other content fields (2 Strings and 1 integer).

3. Create an application which uses HTTP GET method to read a row of data from Supabase. For example, the application will prompt user for a name. Upon clicking “Submit” button, a row of data that corresponds to the supplied name is displayed.
4. Based on the application above, adjust it to allow HTTP POST to be used for inserting data to the table in Supabase.
